

HEURISTICS

Recap: Informed Search

- Define an **evaluation function** $f(n)$ that estimates how promising a given node is.
 - Examples:
 - UCS: priority queue with $f(n) = g(n)$
 - Greedy Best-First: priority queue with $f(n) = h(n)$
 - A*: priority queue with $f(n) = g(n) + h(n)$
- $g(n)$ = distance from start $h(n)$ = estimate to goal

Today

- Reading
 - Read AIMA Ch. 3.5-3.6 (Informed search)
 - Read AIMA Ch. 4.1-4.2 (Local search)

- Objectives
 - A* and heuristic functions
 - (Introduce local search algorithms)

A* search: conditions for optimality

- A heuristic $h(n)$ is **admissible** if it never *overestimates* the cost to the goal

$$0 \leq h(n) \leq h^*(n) \quad h^*(n) \text{ is true cost to goal}$$
- A heuristic $h(n)$ is **consistent** if

$$h(n) \leq c(n, a, n') + h(n') \quad n' \text{ is a successor}$$
- Tree-search version of A* is optimal if $h(n)$ is admissible
- Graph-search version of A* is optimal if $h(n)$ is consistent

Properties of A* search

- A* expands
 - all nodes with $f(n) < C^*$
 - some nodes with $f(n) = C^*$
 - no nodes with $f(n) > C^*$
- Optimally efficient
- Complete if finite number of nodes with $f(n) \leq C^*$

Creating admissible heuristic functions

- How do we construct a heuristic function that doesn't overestimate the cost to the goal?

Goal State

- What are some ideas for heuristic functions?

Creating admissible heuristic functions

- Two-well used heuristics:

- h_1 = number of misplaced tiles
- h_2 = sum of the distances of the tiles from goal positions (Manhattan distance)

	Tiles out of place	Sum of distances out of place									

Why are these admissible?

Creating admissible heuristic functions

- Often admissible heuristics are solutions to **relaxed problems** with fewer restrictions
- A tile can move from square A to square B if
 - A is horizontally or vertically adjacent to B
 - B is blank

Creating admissible heuristic functions

- Often admissible heuristics are solutions to **relaxed problems** with fewer restrictions
- A tile can move from square A to square B if
 - ~~A is horizontally or vertically adjacent to B~~ ← relax the rules
 - ~~B is blank~~
- Induces h_1 heuristic, i.e. number of tiles out of place
 - Allows you to pick up the tiles and place in the correct spot

	Number nodes expanded for solution depth d		
	d = 4	d = 8	d = 12
IDS	112	6384	3.6 million
$A^*(h_1)$	13	39	227

Creating admissible heuristic functions

- Often admissible heuristics are solutions to **relaxed problems** with fewer restrictions
- A tile can move from square A to square B if
 - A is horizontally or vertically adjacent to B ← relax the rules
 - ~~B is blank~~
- Induces h_2 heuristic, i.e. sum of distances to goal position
 - Allows you to move a tile to an adjacent square

	Number nodes expanded for solution depth d		
	d = 4	d = 8	d = 12
IDS	112	6384	3.6 million
$A^*(h_1)$	13	39	227
$A^*(h_2)$	12	25	73

Creating admissible heuristic functions

		Number nodes expanded for solution depth d		
		d = 4	d = 8	d = 12
expands fewer nodes	IDS	112	6384	3.6 million
	A*(h ₁)	13	39	227
	A*(h ₂)	12	25	73

Creating admissible heuristic functions

- Some heuristics are better than others
 - If $h_1(n) \leq h_2(n) \leq h^*(n)$ then h2 **dominates** h1
 - Manhattan distance dominates tiles out of place
 - A-star search using h_2 will never expand more nodes than A-star search using h_1
 - Can combine admissible heuristics using max

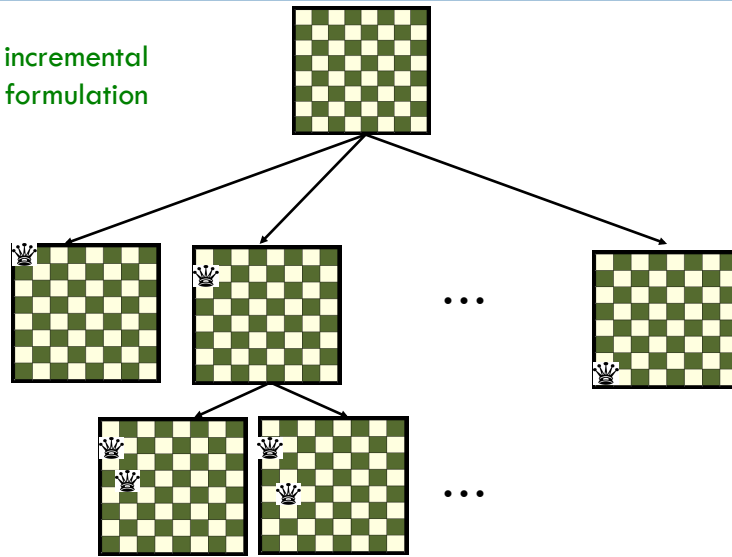

Informed search summary

- Uses additional information to guide search process
 - UCS – cost from start node
 - Greedy best-first – estimate of cost to goal
 - A* uses both cost from start + estimate to goal
 - A* is optimal with admissible/consistent heuristic
- A good heuristic is the key!
 - Consider solutions to relaxed problems

Local Search Algorithms

Recall the N-Queens problem

incremental
formulation

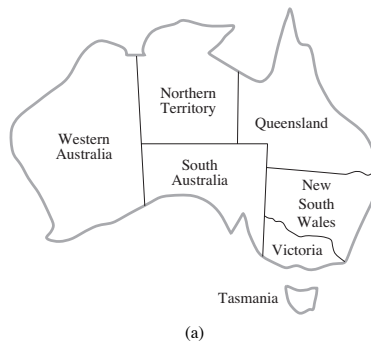

N-Queens alternative approach

complete state
formulation

Map Colorings

Local Search Algorithms

- The basic idea:
 1. Randomly initialize state
 2. If not goal state,
 - a. make local modification to generate neighbor state OR
 - b. enumerate all neighbor states and choose the best
 3. Repeat step 2 until goal state is found (or out of time)
- Requires the ability to *quickly*:
 - ▣ Generate a random (probably-not-optimal) state
 - ▣ Evaluate the quality of a state
 - ▣ Move to other states (well-defined neighborhood function)
